(54) Title: SUBSTRATE WITH PHOTOCATALYTIC FILM AND METHOD FOR PRODUCING THE SAME

(57) Abstract: The surface resistance of a titanium oxide film can be controlled in 10^9 to $10^{13} \Omega/\square$ by coating a titanium oxide film on a substrate by sputtering a target containing metallic titanium under an atmosphere at reduced pressure and then subjecting the film to heat treatment under an oxidizing, inert or reducing atmosphere, depending on the oxygen-deficient state of the film. It is possible that a small amount of niobium oxide is contained in the titanium oxide, or a niobium oxide film is provided as an underlying film.

DESCRIPTION

**SUBSTRATE WITH PHOTOCATALYTIC FILM AND
METHOD FOR PRODUCING THE SAME**

Technical Field

The present invention relates to a substrate on which a photocatalytic film having titanium oxide as a primary component is coated and a method for producing the same.

Background Art

Substrates (articles) on whose surface a photocatalytic film is coated are widely used in, for example, windowpanes of buildings requiring fouling resistance, antibacterial property, and the like, indicator panels of electronic displaying instruments, casings of portable equipment, sanitary installations, frames of medical facilities, apparatus in the field of biotechnology such as DNA analysis, and the like. The substrates on which a photocatalytic film containing titanium oxide as a primary component is coated are widely used in order to provide fouling resistance, antibacterial property, deodorizing function and the like to the such substrate surfaces.

Such photocatalytic films are coated by sputtering processes, and it is known that crystalline titanium dioxide films are preferable as such films in order to increase the photocatalytic activity of the photocatalytic films and make the fouling resistance performance better. However, in order to coat on a substrate a titanium dioxide film having

good crystallinity, there is a problem of requiring heating the substrate to be coated at a temperature of 300°C or more (Japanese Patent Laid-Open No. 10-152396).

In addition, there are known photocatalytic films prepared by irradiating a metallic titanium target with electron beams in an oxidizing atmosphere to coat an amorphous titania (non-crystalline titanium oxide) film on a glass plate, followed by calcination it at a temperature of 400 to 500°C or more to form rutile-typed titania crystal (Japanese Patent Laid-Open No. 10-146251) and processes for photocatalytic films of crystalline titanium dioxide prepared by coating a metallic titanium or titanium oxide film on a glass plate by sputtering, followed by calcination it (Japanese Patent Laid-Open Nos. 10-278165 and 10-146251).

However, coating a photocatalytic film on a substrate heated at high temperatures by a sputtering process that are carried out in an atmosphere at reduced pressure causes releasing impurity gases such as moisture from the inner wall of the heated decompressing container (film-forming chamber container), and therefore has technical problems of being difficult in making reduced-pressure atmosphere good purity. In other words, in order to make reduced-pressure atmosphere good purity necessary to obtain a good photocatalytic activity, a vacuum exhausting system in a big way is required to sputtered-film-forming equipment, causing problems of increasing the cost of coating a photocatalytic film.

In addition, methods of crystallizing the above-mentioned amorphous titanium oxide and metallic titanium films in the air by heating and calcination have problems of poor productivity because of requiring calcination for a sufficient period of time at high temperatures (heat treatment) and expensive calcination equipment and elongating the heating cycle. Furthermore, there are problems of not obtaining readily photocatalytic films with good reproducibility.

Disclosure of the Invention

A subject of the present invention is to solve the above-mentioned problems. A first purpose of the present invention is to provide a substrate on which a photocatalytic film having high photocatalytic activity is coated. A second purpose of the present invention is to provide a method capable of producing a substrate with such photocatalytic film without the need of heating at a high temperature in the film-coating step.

The present invention have been achieved by finding that when a titanium oxide film coated on the surface of a substrate by a sputtering process which is amorphous or at a state where the crystallinity has not sufficiently developed is heated and crystallized with controlling the oxygen-defect state of the film, it can be formed to a photocatalytic film containing titanium oxide as a primary component and having good photocatalytic activity.

An invention described in claim 1 is a substrate with photocatalytic film comprising a substrate and a photocatalytic film coated on the substrate, wherein said photocatalytic film is coated on said substrate by sputtering a target containing titanium in an atmosphere at reduced pressure, contains titanium oxide as a primary component, and has a surface resistance of 10^9 to 10^{13} Ω/\square .

The photocatalytic film having a titanium oxide film as a primary component according to the present invention is a crystalline titanium dioxide film containing anatase-typed crystal and characterized by a controlled oxygen-defect state of the film. In the case that a titanium dioxide film contains an almost stoichiometric amount of titanium and oxygen, its surface resistance is at a level of 10^{15} Ω/\square or more. By contrast, the photocatalytic film according to the present invention is formed to an oxygen-defect state, whereby the surface resistance of the film can be controlled in the range of 10^9 to 10^{13} Ω/\square .

Although the reason is not clear why the degree of the photocatalytic activity of a titanium oxide film depends on the oxygen-defect state of the titanium dioxide film, it is likely that the oxygen deficiency can be contributed to the energy level of the crystalline titanium oxide film.

The relationship between the photocatalytic activity and the surface resistance of the titanium dioxide film indicates that when the surface resistance is more than 10^{13} Ω/\square and the amount of oxygen deficiency is reduced, the

photocatalytic activity is decreased. By contrast, when the surface resistance is less than $10^9 \Omega/\square$, that is, when the oxygen deficiency is present at a more amount than that indicated by $10^9 \Omega/\square$ surface resistance (the oxygen in the titanium oxide film is reduced to a smaller amount than that corresponding to the stoichiometric amount of titanium dioxide), the photocatalytic activity is reduced, if anything. The titanium oxide photocatalytic film according to the present invention has a surface resistance controlled within the range of 10^9 to $10^{13} \Omega/\square$, and therefore has high photocatalytic activity.

The photocatalytic film according to the present invention is coated on a substrate by a sputtering process. The film is coated by employing metallic titanium or a metal having metallic titanium as a primary component as a target, and sputtering it in reduced pressure atmosphere comprising a mixed gas of an inert gas such as argon and oxygen or oxygen gas alone. The controlling of the oxygen deficiency of the titanium oxide film can be achieved by controlling the total pressure of the atmosphere gas and the partial pressure of oxygen during sputtering the target.

Also, the photocatalytic film according to the present invention can be coated by employing, as a target, titanium dioxide that has the stoichiometric composition or is at a state where the oxygen is somewhat more defect than the stoichiometric amount (sometimes referred to as titanium suboxide), and sputtering it in reduced pressure atmosphere

comprising a mixed gas of an inert gas such as argon and oxygen or oxygen gas alone. The controlling of the oxygen deficiency in the titanium oxide film can be achieved by controlling the total pressure of the atmosphere gas and the partial pressure of oxygen during sputtering the target.

According to an invention described in claim 2, in the invention described in claim 1, the surface resistance of the photocatalytic film is controlled so as to be within 10^9 to $10^{13} \Omega/\square$ by heat treatment after coating on the substrate.

In the present invention, the surface resistance can be controlled such that the titanium dioxide film immediately after coating has the resistance range described above, and preferably is controlled in combination with the resistance controlling during coating and the resistance controlling by heat treatment after coating. This can result in the formation of a photocatalytic film having a higher surface hardness.

According to an invention described in claim 3, in the invention described in claim 1 or 2, the heat treatment is carried out such that the contact angle of pure water on the surface of the photocatalytic film is 65° or less. The degree of the photocatalytic activity and practical performance are affected by the hydrophilicity of the film surface. It is preferable that the heat treatment is carried out such that the surface resistance of the photocatalytic film is controlled in the above-mentioned range and the hydrophilicity of the photocatalytic film is reduced. From

this viewpoint, it is preferably that the contact angle of pure water on the surface of the photocatalytic film is 65° or less. In the present invention, the contact angle of pure water refers to a contact angle under the condition where the films are allowed to stand in a dark room for two weeks after the exposure of UV irradiation (the center wave-length of 360 nm, 3 mW/cm²) for 30 min.

According to an invention described in claim 4, in the invention described in any one of claims 1 to 3, the photocatalytic film contains, as a by-component, any one of niobium oxide, aluminum oxide, iron oxide and nickel oxide. Incorporating these metals into the crystal lattice of titanium oxide can change the energy level of the crystal lattice, thereby resulting in the formation of a film having higher photocatalytic activity.

According to an invention described in claim 5, in the invention described in any one of claims 1 to 4, a niobium oxide film, aluminum oxide film, iron oxide film or nickel oxide film is interposed as an underlying film between the substrate and the photocatalytic film. For example, in the case that a niobium oxide film is the underlying film, a photocatalytic film obtained by laminating and coating a niobium oxide film and a titanium oxide film on the substrate and subsequently heat treating has the niobium diffused from the interface between the titanium oxide and niobium oxide films into the titanium oxide film, thereby resulting in

higher photocatalytic activity. According to an invention described in claim 6, in the invention described in claim 5, a niobium oxide film is preferable among these oxide films.

Substrates to be employed in the present invention are not limited to specified materials and shapes. Any material can be used which does not deteriorate during coating a film by sputtering, and on optionally heating the substrate and on the heat treatment after coating. According to an invention described in claim 7, in the invention described in any one of claims 1 to 6, for example, substrates of glass, ceramic, resin or metal can be used. According to an invention described in claim 8, in the invention described in claim 7, in particular, for glass plate containing alkali components such as soda lime silicate glass plate, the underlying film can prevent the decrease in the photocatalytic activity by diffusing the alkali components of the glass into the titanium oxide photocatalytic film.

An invention described in claim 9 is a method for producing a substrate with photocatalytic film, comprising the steps of coating a photocatalytic film containing titanium oxide as a primary component on a substrate by sputtering a target containing titanium in an atmosphere at reduced pressure, and subjecting the photocatalytic film after said coating to heat treatment.

According to an invention described in claim 10, in the invention described in claim 9, for sputtering target used for sputtering in the present invention, sintered molded

articles of fine powder of metallic titanium or titanium dioxide can be utilized. In the case of employing metallic titanium as the target, it is possible to increase the photocatalytic activity to a higher extent by incorporating a small amount of niobium, iron, aluminum, nickel or the like and changing the energy level of the resulting titanium dioxide photocatalytic film. In the case of employing sintered articles of titanium oxide as the target, it is possible to use sintered articles of fine powder of titanium dioxide, sintered molded articles of fine powder of titanium suboxide (having a somewhat smaller O/Ti ratio than that of titanium dioxide).

According to an invention described in claim 11, in the invention described in claim 9 or 10, an oxygen atmosphere, a mixed gas atmosphere of oxygen and an inert gas such as argon and the like can be employed as the atmosphere at reduce pressure during coating the film. This is intended for the crystallization of the film coated on the substrate and the increase in the crystallinity of the film, and results in the controlling of the oxygen-defect state, as expressed by the surface resistance, in the range of 10^9 to $10^{13} \Omega/\square$.

According to an invention described in claim 12, in the invention described in claims 9 to 11, in the case that the surface resistance of the coated film is more than $10^{13} \Omega/\square$, the heat treatment is carried out in an inert or reducing atmosphere.

For the films having a surface resistance after coating of more than $10^{13} \Omega/\square$, the increase in the photocatalytic activity can be achieved by increasing the oxygen deficiency in the films. To this purpose, the atmosphere during the heat treatment is an inert or reducing atmosphere.

According to an invention described in claim 13, in the invention described in claim 12, the inert atmosphere is exemplified by a nitrogen-gas atmosphere, and an inert-gas atmosphere such as argon, or a vacuumed space where the pressure is reduced to a sufficient degree. An atmosphere containing hydrogen gas can be employed as the reducing atmosphere.

According to an invention described in claim 14, in the invention described in claim 12 or 13, the surface resistance of the photocatalytic film is decreased to a value of $10^9 \Omega/\square$ or more.

According to an invention described in claim 15, in the invention described in claim 14, it is likely that the generation, increase of the oxygen deficiency in the film are effected by drawing the oxygen having unstable or weak linkage with titanium from the inside of the film to the outside. In order to increase the photocatalytic activity, it is preferable that the surface resistance value of the film is decreased to $10^9 \Omega/\square$ or more, and more preferable to $10^{10} \Omega/\square$ or more.

According to an invention described in claim 16, in the invention described in claim 9, in the case that the surface

resistance of the photocatalytic film coated on by a sputtering process is less than $10^9 \Omega/\square$, the heat treatment is carried out under an oxidizing atmosphere.

The surface resistance of the film of less than $10^9 \Omega/\square$ indicates that the film is rich in oxygen deficiency therein and has a small photocatalytic activity. In this case, the photocatalytic activity can be increased by decreasing the amount of the oxygen deficiency in the film, that is, by increasing a surface resistance value corresponding to the amount of the oxygen deficiency. The oxidizing atmosphere employed can be an atmosphere containing oxygen or ozone, and the heat treatment in the air is most preferable from an economical viewpoint.

According to an invention described in claim 17, in the invention described in claim 16, the surface resistance value of the photocatalytic film is increased to $10^{13} \Omega/\square$ or less.

According to an invention described in claim 18, in the invention described in claim 17, it is preferable that the surface resistance value of the film is increased to $10^9 \Omega/\square$ or more, and more preferable to $10^{10} \Omega/\square$ or more, in order that the oxygen deficiency in the film is disappeared and the photocatalytic activity is increased.

According to an invention described in claim 19, in the invention described in claims 9 to 18, the heating temperature in the heat treatment step is from 200 to 350°C. According to an invention described in claim 20, in the invention

described in claims 9 to 18, it is preferable that the heating temperature is from 200 to 300°C.

According to claims 19 and 20, it is possible to increase the degradation ratio of triolein of the photocatalytic film and the hydrophilicity of the film surface.

According to an invention described in claim 21, in the invention described in claims 9 to 20, the sputtering target contains any one of niobium, aluminum, iron and nickel as a by-component. It is possible to contain more than one by-component.

According to an invention described in claim 22, in the invention described in claim 21, it is preferable that in the case that a target to be used is a metallic target, these metals are contained at 0.1 to 3 % by weight of the metallic titanium. The photocatalytic film obtained by sputtering such a metallic target in an oxygen-containing atmosphere has the oxygen-defect state that can be controlled by heat treatment in a similar way to as in the single composition of titanium oxide.

An invention described in claim 23, in the invention described in claims 9 to 22, comprises the step of coating any one of niobium oxide film, aluminum oxide film, iron oxide film and nickel oxide film on the substrate by sputtering a target containing any one of niobium, aluminum, iron and nickel in an atmosphere at reduced pressure, before coating the photocatalytic film containing titanium oxide as a primary component.

For example, in the case of employing a niobium oxide film, a laminate of the niobium oxide and titanium oxide films laminated on the substrate has the niobium diffused into the titanium oxide film by the heat treatment, resulting in affecting the energy level of the photocatalytic film, and thus improving the photocatalytic activity. According to an invention described in claim 24, in the invention described in claims 9 to 23, it is preferable that the substrate temperature is less than 200°C during coating the photocatalytic film on the substrate by sputtering.

Brief Description of the Drawings

Figure 1 shows a cross-sectional view of one example of the substrate with photocatalytic film according to the present invention;

Figure 2 shows a graph illustrating the relationship between the degradation ratio of triolein and the surface resistance of the titanium oxide photocatalytic film;

Figure 3 shows a graph showing effects of the heat treatment temperature on the degradation ratio of triolein; and

Figure 4 shows a graph showing effects of the heat treatment temperature on the contact angle of water on the photocatalytic film surface.

Best Mode of Carrying Out the Invention

Embodiments of the present invention will be described as follows. Figure 1 shows a cross-sectional view of one example of the substrate with photocatalytic film according to the present invention, wherein the substrate with photocatalytic film 1 has a niobium oxide underlying film 4 and a titanium oxide photocatalytic film 3 on the film 4, the underlying and photocatalytic films being laminated and coated on the surface of a glass plate 2. Figure 2 shows a graph illustrating the relationship between the photocatalytic activity and the surface resistance of the titanium oxide photocatalytic film. Figure 3 shows a graph illustrating effects of the heat treatment temperature on the photocatalytic activity. Figure 4 shows a graph illustrating effects of the heat treatment temperature on the photocatalytic film hydrophilicity.

As a sputtered-film-forming equipment for coating the photocatalytic film of the present invention on a substrate, known sputtered-film-forming equipment can be used which has a mechanism allowing argon and oxygen at a controlled flow rate to be introduced into the film forming chamber and the function of vacuuming the film forming chamber by the vacuum pump and of stably keeping an atmosphere at a given reduced pressure.

For processes for generating glow discharge to sputter a target can be used known processes. That is, it is possible to use known processes such as direct current sputtering processes, high frequency sputtering processes, and PMS

(Pulse Magnetron Sputtering) process in which sputtering is carried out while applying the voltage to cathodes arranged side by side with alternately inverting the polarity of the applied voltage and removing charges charged on the target surface.

The following describes the photocatalytic film according to the present invention with the relationship between the atmosphere gas composition of mixed gasses consisting of oxygen and argon and the oxygen deficiency in the resulting film when the total pressure of the atmosphere during sputtering, usually employed by the Pulse Magnetron Sputtering process, is set to 0.4 Pa. A film after coating which can be subjected to heat treatment under an oxidizing atmosphere to increase the photocatalytic activity is referred to "an oxygen-deficient film" hereinafter, in the sense that the oxygen defect is abundant. On the other hand, a film immediately after coating which can be subjected to reductive heat treatment under an inert or reducing atmosphere to increase the photocatalytic activity is to be referred to "an oxygen-rich film" hereinafter, since the oxygen defect is at a small amount, and the oxygen is contained to a relatively high extent, as opposed to the above-mentioned oxygen-deficient film.

(1) In the case of employing titanium-metal-based targets

For films immediately after coating, films having a various range of the oxygen content in the film are coated,

such as from a titanium oxide film having an almost stoichiometric composition to an oxygen-deficient film that is relatively rich in the oxygen defect. In order to carry out sputtering in a reactive manner with oxygen, it is preferable that the oxygen of the atmosphere usually is contained at 60 to 65 % by volume or more. The oxygen-rich film according to the present invention can be obtained under the atmosphere containing about 80 % or more oxygen. On the other hand, when the oxygen content is 70 to 75 % by volume or less, an oxygen-deficient film is formed, which in turn are subjected to oxidative heat treatment. The relationship between the oxygen-defect state of the film immediately after coating and the composition of the sputtering gas (oxygen content) is uniquely determined by no means, and depends on the total pressure during sputtering, the coating speed (coating rate) of the reactive coating, and the presence of residual impurity gasses and other in the vacuum.

(2) In the case of employing targets of titanium dioxide-based fine-powder sintered articles

A compressed target is applied to, for example, heat treatment at a temperature of 1300°C or more under an inert atmosphere, resulting in the formation of a conductive titanium suboxide target, which becomes capable of sputtering by direct current glow discharge. In the case that a titanium oxide-base sintered target is used which is treated to such an extent that such a direct current sputtering is possible, a titanium dioxide film close to an almost stoichiometric

composition is coated on a substrate. In this case, the oxygen of the atmosphere gas can be usually supplied as a minor component.

A film coated under the sputtering atmosphere having an oxygen content of 30 to 40 % by volume is already an oxygen-rich films, which can have an increased photocatalytic activity by heat treating under an inert or reducing atmosphere after coating. By contrast, in the case of the oxygen being 4 to 5 % by volume or less, the resulting film is an oxygen-deficient film, which can be formed into a film having good photocatalytic activity by oxidative heat treatment. The percent oxygen content of this atmosphere and the oxygen-defect state of the resulting film are uniquely determined by no means, because of depending on the coating rate and the total pressure, and in addition the amount of impurity gasses.

The substrate temperature during coating the photocatalytic film of the present invention on the substrate by sputtering is preferably less than 200°C at which its crystallization does not take place to a great extent during coating. Usually, it is preferable to carry out at not more than 150°C or at room temperature (the substrate is not heated).

The crystallization and controlling of the resistance of the coated films are carried out in the heat treatment step of the present invention. In order to carry out the crystallization and controlling of the resistance such that the photocatalytic activity is effectively increased, the

heating temperature is preferably 150°C or more. For the photocatalytic film coated by a sputtering process, this can result in the increase in the crystallization and the controlling of a predetermined surface resistance for a short period. The temperature is preferably 200°C or more, also from the viewpoint of increasing the hydrophilicity of the photocatalytic film surface. As pieced together from these viewpoints, the heat treatment temperature is preferably 200°C or more.

At the heat treatment temperature of more than 400°C, further crystallization of the photocatalytic film takes place, but changes such as unusual crystal growth, and diffusion and segregation of dopants are brought about in the catalyst film, thus leading to the decrease in the photocatalytic activity, if anything. Therefore, the heat treatment temperature is preferably 350°C or less, and more preferably 300°C or less.

For atmospheres during the heat treatment, an oxygen containing atmosphere, for example, air and an ozone containing atmosphere, can be used when oxidative crystallization is carried out to increase the surface resistance. On the other hand, in order that non-oxidative crystallization is carried out and the surface resistance is controlled at an approximately same value or otherwise decreased, an atmosphere containing an inert gas such as nitrogen, argon, helium, neon, and a reducing atmosphere containing hydrogen (for example, a mixed gas of nitrogen and

hydrogen, a hydrogen gas containing 5 to 50 % by volume carbon monoxide, and others) can be used. In addition, as an atmosphere having the same effect as an inert atmosphere, an atmosphere at reduced pressure (vacuumed atmosphere) can be also used. In this case, there are advantages of allowing the photocatalytic film coated on a substrate by a sputtering process to be subjected to the heat treatment, as it is, without discontinuation under the vacuumed atmosphere in the sputtering apparatus.

The present invention will be described in detail by means of Examples and Comparative Examples as follows. The methods of coating a photocatalytic film and of heat treatment are set forth as follows.

(Sputtering and Coating Conditions)

A. Substrate

Float glass plates having 2 mm thickness and composed of soda lime silicate.

B. Coating of a Titanium Dioxide Film

1) Target

(1) Metallic titanium, 99.99 %, (referred to as Ti).

(2) Metallic titanium containing 0.5 % by weight of metallic niobium (referred to as TiNb).

(3) Metallic titanium containing 0.5 % by weight of metallic aluminum (referred to as TiAl).

(4) Metallic titanium containing 0.3 % by weight of metallic iron (referred to as TiFe).

(5) Metallic titanium containing 0.3 % by weight of metallic nickel (referred to as TiNi).

(6) An article obtained by compressing titanium dioxide fine powder in the air and heat treating under a nitrogen atmosphere to form a state that is somewhat more deficient in oxygen than the stoichiometric composition of titanium dioxide (referred to as TiO_x in Table).

(7) A molded and processed article obtained by a similar treatment (6) of mixed powders of 99 % by weight of titanium dioxide (TiO_2) fine powder and 1 % by weight of niobium oxide (Nb_2O_5) fine powder (referred to as TiNbO_x in Table).

2) Glow discharge: direct current sputtering

3) Atmosphere during sputtering

The total pressure was adjusted to 0.4 Pa, and the atmosphere during sputtering was argon, oxygen, or a mixed gas of argon and oxygen.

4) Substrate temperature during sputtering

Room temperature (without heating).

C. Coating of an Underlying Film of Niobium Oxide

1) Metallic niobium target: metallic niobium, 99.99% (referred to as Nb in Table).

2) Glow discharge: direct current sputtering.

3) Atmosphere during sputtering

The total pressure was adjusted to 0.4 Pa, and the atmosphere during sputtering was 100 % oxygen.

4) Substrate temperature during sputtering

Room temperature (without heating).

D. Heat Treatment

The furnace used in the heat treatment is an electric furnace capable of vacuuming down to 0.4 Pa or less and allowing an atmosphere gas to enter the furnace through the inlet port to atmospheric pressure. The atmosphere gas was introduced into the furnace and substituted for the previous atmosphere for more than five minutes, and the atmosphere within the furnace was heated at a rate of rising temperature of 10°C/min. while further flowing the atmosphere gas into the furnace, so that the furnace was filled with the atmosphere at a predetermined heat treatment temperature, and then maintained for one hour. After that, the furnace was cooled gradually to room temperature with flowing the atmosphere gas. An oxidizing atmosphere (surface resistance increasing treatment) employed air, an inert atmosphere (surface resistance decreasing treatment) employed nitrogen, and an reducing atmosphere (surface resistance decreasing treatment) employed a mixed gas of 75 % by volume of nitrogen and 25 % by volume of hydrogen.

(Evaluation of Photocatalytic Films)

A. Photocatalytic Activity

Triolein was coated on the surface of the films so as to be at 0.1 mg/cm², and irradiated with ultra violet radiation at a power of 3 mW/cm² for 46 hours. The degradation ratio of the coated triolein was calculated from weight measurements of the coated and remaining amounts.

B. Surface Resistance

In accordance with the JIS method (C2141).

C. Hydrophilicity

The photocatalytic films were irradiated with UV (the central wavelength: 360 nm, 3 mW/cm²) for 30 min. and the contact angle of pure water on the surface under the condition was measured where the film were allowed to stand in a dark room for two weeks.

D. Crystallinity of the Films

Determination was carried out on a Rigaku Denki X-ray diffractometer.

Example 1

A sample was obtained by employing a sintered molded article of titanium suboxide as the target and coating a photocatalytic film having a thickness of 500 nm with a gas composition of 50 % by volume of oxygen and 50 % by volume of argon. The surface resistance of the resulting photocatalytic film was shown to have a high surface resistance of $1 \times 10^{14} \Omega/\square$ (Table 1). When this film was heat treated under the inert atmosphere, the surface resistance was decreased to $1 \times 10^{13} \Omega/\square$. It is likely that this decrease in the resistance (increase in the conductivity) is due to increasing electrons contributing to the conductivity by drawing the oxygen from the coated film and increasing the oxygen defect in the crystal of the titanium dioxide film, and due to increasing their mobility by the acceleration of the crystallization of the film. By measuring

photocatalytic activity, the degradation ratio of triolein was 47 %, which is a practically useful value for imparting fouling resistance and antibacterial property.

Example 2

Sample 2 was prepared in a similar way as in Example 1, except that the atmosphere during the heat treatment was changed to the reducing atmosphere. A similar heat treatment of this photocatalytic film as in Example 1 resulted in decreasing the surface resistance to $1 \times 10^{10} \Omega/\square$, and the degradation ratio of triolein had a good value of 63 %.

Example 3

A photocatalytic film was coated on a glass plate in a similar way as in Example 1, except that metallic titanium was employed as a target and the atmosphere during sputtering was 90 % by volume of oxygen. The surface resistance immediately after coating was $1 \times 10^{14} \Omega/\square$, whereas the heat treatment under the inert atmosphere decreased the surface resistance to $5 \times 10^{12} \Omega/\square$. The degradation ratio of this photocatalytic film had a high value of 53 %.

Example 4

A photocatalytic film was coated on a glass plate in a similar way as in Example 3, except that the oxygen of the atmosphere during sputtering was 70 % by volume. The surface resistance immediately after coating was $2 \times 10^9 \Omega/\square$, and

it was estimated that this film is a film rich in oxygen defect. The heat treatment of this film under the oxidizing atmosphere increased the surface resistance to $5 \times 10^{11} \Omega/\square$, which means that the amount of the oxygen defect was decreased. The degradation ratio of triolein of this photocatalytic film had a high value of 60 %.

Example 5

A photocatalytic film was coated on a glass plate in a similar way as in Example 1, except that the oxygen of the atmosphere during sputtering was 4 % by volume and the heat treatment was carried out under the oxidizing atmosphere. This film had a small surface resistance of $5 \times 10^7 \Omega/\square$ and was found to be a film having a large amount of the oxygen defect. When the oxidative crystallization of this film was carried out under the oxidizing atmosphere, the surface resistance was increased by approximately three orders, to $4 \times 10^{10} \Omega/\square$. By measuring the photocatalytic activity of this film, the degradation ratio of triolein was 60 %.

[Table 1]

Example	Target	Oxygen of the atmosphere during sputtering (%)	Surface resistance immediately after coating (Ω/\square)	Heat treatment		Photocatalytic activity Degradation ratio of triolein (%)
				Atmosphere	Surface resistance (Ω/\square)	
(Example)						
1	TiOx	50	1×10^{14}	inert	1×10^{13}	47
2	TiOx	50	1×10^{14}	reductive	5×10^{10}	63
3	Ti	90	1×10^{14}	inert	5×10^{12}	53
4	Ti	70	2×10^9	oxidative	5×10^{11}	63
5	TiOx	4	5×10^7	oxidative	4×10^{10}	60
6	Ti	75	1×10^{12}	inert	1×10^{10}	55
7	TiOx	10	3×10^{10}	oxidative	4×10^{12}	53
8	TiOx	15	3×10^{12}	inert	7×10^{11}	65
9	Ti	95	4×10^{14}	reductive	3×10^{11}	65
(Comparative Example)						
1	Ti	68	7×10^8	inert	5×10^7	5
2	Ti	80	1×10^{13}	oxidative	1×10^{14}	20
3	TiOx	50	1×10^{14}	oxidative	1×10^{15}	5
4	TiOx	4	5×10^7	inert	4×10^6	1 - 3
5	TiOx	10	3×10^{10}	inert	3×10^8	30
6	Ti	100	7×10^{14}	not applied	7×10^{14}	5

Example 6

A sample in which a photocatalytic film was coated on a glass plate in a similar way as in Example 3 was produced, except that the oxygen content of the atmosphere during sputtering was changed. The photocatalytic film of this sample had a surface resistance of $1 \times 10^{12} \Omega/\square$ and a high degradation ratio of triolein of 57 % for the film immediately after coating. When this photocatalytic film was heat treated under the inert gas atmosphere, the surface resistance was decreased by approximately two orders, to $1 \times 10^{10} \Omega/\square$, but had an approximately same photocatalytic activity of 55 %. From these results, it has been found that

even if the heat treatment is not applied, the controlling of the surface resistance of the titanium oxide film could produce a film having good photocatalytic activity.

Example 7

A sample in which a photocatalytic film was coated on a glass plate as in a similar way as in Example 5 was produced, except that the oxygen content of the atmosphere during sputtering was changed. Evaluation results of the photocatalytic film of this sample are shown in Table 1.

Example 8

A sample in which a photocatalytic film was coated on a glass plate as in a similar way as in Example 1 was produced, except that the oxygen content was changed during sputtering. Evaluation results of the photocatalytic film of this sample are shown in Table 1.

Example 9

A titanium oxide film having a thickness of 500 nm was coated on a glass plate by employing metallic titanium as the target and 95 % by volume of oxygen as the atmosphere gas during sputtering. A photocatalytic film of this sample was obtained by heat treating this film under the reducing atmosphere. The surface resistance of the film immediately after coating was $4 \times 10^{14} \Omega/\square$, whereas the heat treatment under the reducing atmosphere resulted in the decrease to 3

$\times 10^{11} \Omega/\square$ by approximately three orders. This photocatalytic film had a high degradation ratio of 65 %.

Comparative Example 1 (Corresponding to Example 3)

A photocatalytic film was coated on a glass plate in the conditions shown in Table 1. The surface resistance of this film was $7 \times 10^8 \Omega/\square$. When this film was heat treated under the reducing atmosphere, the surface resistance was decreased by approximately one order, to $5 \times 10^7 \Omega/\square$, and a film having an extremely abundant amount of the oxygen defect was formed. This film had a small degradation ratio of triolein of 5%, and was found to have practically poor usefulness.

Comparative Example 2 (Corresponding to Example 4)

A photocatalytic film was coated on a glass plate in the conditions shown in Table 1. The surface resistance of this film was $1 \times 10^{13} \Omega/\square$. When this film was heat treated under the oxidizing atmosphere, the surface resistance was increased by approximately one order, to $1 \times 10^{14} \Omega/\square$ and the amount of the oxygen defect was decreased. The degradation ratio of triolein of this film was decreased to 20 %.

Comparative Example 3 (Corresponding to Example 5)

A photocatalytic film was coated on a glass plate in the conditions shown in Table 1. The surface resistance of this film was $1 \times 10^{14} \Omega/\square$. When this film was heat treated under the oxidizing atmosphere, the surface resistance was

increased by one order, to $1 \times 10^{15} \Omega/\square$ and a film having a smaller amount of the oxygen defect was formed, compared with the sample of Comparative Example 2. This film had a much smaller degradation ratio of triolein of 5 %, than that of the sample of Comparative Example 2.

Comparative Example 4 (Corresponding to Example 1)

A photocatalytic film was coated on a glass plate in the conditions shown in Table 1. The surface resistance of this film was $5 \times 10^7 \Omega/\square$. When this film was heat treated under the inert atmosphere, the surface resistance was decreased to $4 \times 10^6 \Omega/\square$, which is approximately one order smaller than before the heat treatment. This sample was a sample having a larger amount of the oxygen defect, compared with the sample of Example 2. This film had an extremely small degradation ratio of triolein of 1 to 3 %.

Comparative Example 5 (Corresponding to Example 1)

A photocatalytic film was coated on a glass plate in a similar way as in Example 7. The surface resistance of this film was $3 \times 10^{10} \Omega/\square$. When this film was heat treated under the inert atmosphere, the surface resistance was decreased to $3 \times 10^8 \Omega/\square$, which was smaller than before the heat treatment. This sample had a film having a larger amount of the oxygen defect, compared with the sample of Example 7. This film has a degradation ratio of triolein of 30 %.

Comparative Example 6 (without heat treatment)

A titanium oxide film was coated on a glass plate by employing metallic titanium as the target and 100 % oxygen as the atmosphere during sputtering. This film has a degradation ratio of triolein of 5 %, and was found to have little photocatalytic activity.

Since photocatalytic films shown in Table 1 were coated at room temperature, each of them had such a degree that little or weak diffraction peaks by the crystal were observed, whereas the heat treatment resulted in observed diffraction peaks by the crystal, from X-ray diffraction analysis. That is, it has been found that the heat treatment can bring about crystallization.

Figure 2 is a plot wherein the surface resistance of the films after the heat treatment is plotted on the abscissa axis and the degradation ratio of triolein on the ordinate axis, for samples obtained in Table 1. It has been found from Figure 2 that the degradation ratio of triolein can be increased by controlling the oxygen-defect state of the titanium oxide film such that the surface resistance value of the photocatalytic film is $1 \times 10^9 \Omega/\square$ to $1 \times 10^{13} \Omega/\square$, and more preferably $1 \times 10^{10} \Omega/\square$ to $1 \times 10^{12} \Omega/\square$.

Example 10 (Photocatalytic Activity and Heat Treatment Temperatures)

For titanium oxide films coated on a glass plate at room temperature in a similar way as in Example 4, effects on the

degradation ratio of triolein of temperatures and times of the heat treatment in the air were examined. The temperatures were at eight levels of 100°C, 150°C, 200°C, 250°C, 300°C, 350°C, 400°C, and 450°C, with two levels of 1 hour and 3 hours at each temperature. The results are shown in Figure 3.

From Figure 3, the degradation ratio of triolein had a maximum at a temperature of about 250°C for both treating periods. In addition, the degradation ratio of triolein was increased in the temperature range of 150°C to 300°C for both treating periods. For the heat treatment at temperatures of 450°C or higher, however, it has been found that the degradation ratio of triolein was decreased, if anything, to such a degree that the values were almost the same as those before heating. It is believed that enough oxidation takes place due to high temperatures, resulting in the oxygen defect exceeding an appropriate range. By contrast, when the heat treatment is carried out at 150 to 350°C, the crystallization can be achieved without decreasing the oxygen defect in the titanium oxide film.

Example 11 (Hydrophilicity and Heat treatment Temperatures)

For titanium oxide films coated on a glass plate at room temperature in the same way as in Example 4, effects of heating temperatures on the contact angle of pure water on the surface of the photocatalytic films were determined when the heat treatment was carried out under the air and the nitrogen atmosphere for one hour, respectively. Results are shown in

Figure 4, in which the heat treatment temperatures were at four levels of 150°C, 250°C, 350°C, and 450°C.

The contact angle of water on the surface of the photocatalytic film before the heat treatment was 78°. When the heat treatment was carried out under the air, at heat treating temperatures of up to 150°C, with the increasing temperature, the contact angle of water was monotonously decreased to 63° and the hydrophilicity was increased. When the heat treating temperature was further increased up to 350°C, the contact angle was not decreased to a great extent and the hydrophilicity was not improved. At temperatures of more than 350°C, the hydrophilicity was slightly increased (the contact angle was decreased). On the other hand, in the case of the nitrogen atmosphere, the hydrophilicity was monotonously increased as the heat treatment temperature was increased. As understood from Figures 3 and 4, it is preferable that the heat treatment temperature is in the range of 200°C to 350°C in order to increase the photocatalytic activity and effectively the hydrophilicity.

Examples 12 and 13 (Experiments of adding niobium oxide impurity)

A photocatalytic film containing titanium oxide as a primary component was coated on a glass plate and heat treated under the conditions shown in Table 2 employing a sintered molded article of mixed powders of titanium oxide and niobium oxide as the target. Results are shown in Table 2. From Table

2, it is recognized that the degradation ratio of triolein can be further increased by incorporating niobium oxide into titanium oxide.

Examples 14 to 16 (Experiments of adding other metal oxide impurity)

A film containing titanium oxide as a primary component was coated on a glass plate under the same atmosphere during sputtering as in Example 4, employing three metallic targets, in which either aluminum, iron or nickel was added to metallic titanium. Table 2 shows results obtained by evaluating the photocatalytic films of the samples that were prepared by heat treating the coated films under the same oxidizing atmosphere as in Example 4. From these results, it has been found that when aluminum, iron or nickel is contained in the titanium oxide film as minor impurity, the photocatalytic activity can be slightly increased.

[Table 2]

Example	Target	O ₂ in the atmosphere during sputtering (%)	Surface resistance immediately after coating (Ω/\square)	Post-heat treatment		Photocatalytic activity Degradation ratio of triolein (%)
				Atmosphere	Surface resistance (Ω/\square)	

(Example)						
12	TiNbOy	10	8×10^{12}	inert	1×10^{11}	65
13	TiNbOy	4	7×10^8	oxidative	7×10^{10}	63
14	TiAl	70	2×10^9	oxidative	1×10^{11}	68
15	TiFe	70	2×10^9	oxidative	2×10^{11}	69
16	TiNi	70	2×10^9	oxidative	1×10^{11}	67

Example 17 (Experiments on laminated structures)

An underlying film of niobium oxide was coated on a glass plate so as to be 10 nm in thick. After that, a titanium oxide film with a thickness of 250 nm was coated on the niobium oxide film by employing metallic titanium as the target and reactive sputtering under the atmosphere of 90 % by volume of oxygen, as in Example 3. The photocatalytic film having this laminated structure was heat treated under the air atmosphere at 250°C for 1 hour. The resulting photocatalytic film had a degradation ratio of triolein of 65 %, which is higher than that of Example 3, as indicated in Table 3.

[Table 3]

Example	Target	Laminated structure	Surface resistance immediately after coating (Ω/\square)	Heat treatment		Photocatalytic activity Degradation ratio of triolein (%)
				Atmosphere	Surface resistance (Ω/\square)	
(Example) 17	Nb/Ti	Nb ₂ O ₅ /TiO ₂	2×10 ¹⁴	inert	2×10 ¹²	65

Example 18

For films having the laminated structure coated on a glass plate in Example 17, effects on the photocatalytic activity of the heating temperature of the heat treatment under the inert atmosphere were examined. In the case that the treating time was one hour and the temperatures were 100°C, 200°C, 300°C, and 450°C, results are shown in Table 4, as Samples 18A, 18B, 18C, 18 D and 18E, along with the results of the sample of Example 17 for comparison. The results of Table 4 indicate that the degradation ratio of triolein can

be slightly increased by employing the laminated structure of niobium oxide and titanium oxide films. Although this reason is not clear, it is believed that the niobium diffused and entered from the interface of the titanium oxide film by the heat treatment took an optimal coordination state in the crystal of titanium dioxide.

[Table 4]

Example	Laminated Structure	Surface resistance immediately after coating (Ω/\square)	Heat Treatment for 1 hour		Surface resistance (Ω/\square)	Photocatalytic activity Degradation ratio of triolein (%)
			Atmosphere	Temperature ($^{\circ}\text{C}$)		
(Example)						
Sample 18A	$\text{Nb}_2\text{O}_5/\text{TiO}_2$	2×10^{14}	not applied		2×10^{14}	20
Sample 18B	$\text{Nb}_2\text{O}_5/\text{TiO}_2$	2×10^{14}	inert	100	1×10^{14}	22
Sample 18C	$\text{Nb}_2\text{O}_5/\text{TiO}_2$	2×10^{14}	inert	200	5×10^{12}	53
Sample 17	$\text{Nb}_2\text{O}_5/\text{TiO}_2$	2×10^{14}	inert	250	1×10^{12}	68
Sample 18D	$\text{Nb}_2\text{O}_5/\text{TiO}_2$	2×10^{14}	inert	300	9×10^9	63
Sample 18E	$\text{Nb}_2\text{O}_5/\text{TiO}_2$	2×10^{14}	inert	450	1×10^8	27

From the explanation described above, it is clear that the surface resistance of the titanium oxide film is associated with the oxygen-defect state and the crystallinity, which significantly contribute to its photocatalytic activity. It is believed that incorporation of added impurity into the crystalline film of titanium oxide can change its energy level (band structure), thereby leading to increasing its photocatalytic activity.

Industrial Applicability

The photocatalytic film of titanium oxide coated on a substrate by a sputtering process according to the present invention has a surface resistance controlled in the range of 10^9 to $10^{13} \Omega/\square$, and therefore high photocatalytic activity.

In addition, it is possible to increase the surface hardness of the film by carrying out the controlling of the surface resistance by the crystallization of the film associated with the heat treatment.

Furthermore, it is possible to increase the photocatalytic activity by adding a small amount of impurity to the titanium oxide photocatalytic film. Also, it is possible to increase the photocatalytic activity by coating an underlying film of the titanium oxide photocatalytic film.

The method of the present invention comprises the steps of coating a photocatalytic film having titanium oxide as a primary component on a substrate by a sputtering process, and subjecting the film to heat treatment after coating. According to the method of the present invention, the film obtained by the coating step can have its surface resistance controlled in a pre-determined range, so that the oxygen-defect state in the film can be controlled and a substrate with photocatalytic film having high photocatalytic activity can be produced with good reproductivity.

In addition, since a photocatalytic film can be coated without heating a substrate, it is unnecessary to provide

sputtered-film-forming equipment with large heating and vacuum mechanisms, and coating can be carried out economically.

CLAIMS

1. A substrate with photocatalytic film comprising a substrate and a photocatalytic film coated on the substrate, wherein said photocatalytic film is coated on said substrate by sputtering a target containing titanium in an atmosphere at reduced pressure, contains titanium oxide as a primary component, and has a surface resistance of 10^9 to 10^{13} Ω/\square .
2. The substrate with photocatalytic film according to claim 1, wherein the surface resistance of the photocatalytic film is controlled by heat treatment after coating on the substrate.
3. The substrate with photocatalytic film according to claim 2, wherein the heat treatment is carried out such that the contact angle of pure water on the surface of the photocatalytic film is 65° or less.
4. The substrate with photocatalytic film according to any one of claims 1 to 3, wherein the photocatalytic film contains, as a by-component, any one of niobium oxide, aluminum oxide, iron oxide, and nickel oxide.
5. The substrate with photocatalytic film according to any one of claims 1 to 4, wherein any one of niobium oxide, aluminum

oxide film, iron oxide film and nickel oxide film is provided as an underlying film between the substrate and the photocatalytic film.

6. The substrate with photocatalytic film according to claim 5, wherein the underlying film is a niobium oxide film.

7. The substrate with photocatalytic film according to any one of claims 1 to 6, wherein the substrate is selected from glass, ceramic, resin and metal.

8. The substrate with photocatalytic film according to claim 7, wherein the substrate is glass containing alkali component.

9. A method for producing a substrate with photocatalytic film, comprising the steps of coating a photocatalytic film containing titanium oxide as a primary component on a substrate by sputtering a target containing titanium in an atmosphere at reduced pressure, and subjecting the photocatalytic film after said coating to heat treatment.

10. The method for producing a substrate with photocatalytic film according to claim 9, wherein the target is a sintered molded article of fine powder of metallic titanium, titanium dioxide, or titanium suboxide.

11. The method for producing a substrate with photocatalytic film according to claim 9 or 10, wherein the atmosphere at reduced pressure is an oxygen atmosphere or a mixed atmosphere of oxygen and an inert gas such as argon.

12. The method for producing a substrate with photocatalytic film according to any one of claims 9 to 11, wherein in the case that the surface resistance of the photocatalytic film after said coating is more than $10^{13} \Omega/\square$, the heat treatment is carried out in an inert or reducing atmosphere.

13. The method for producing a substrate with photocatalytic film according to claim 12, wherein the inert atmosphere is a nitrogen-gas atmosphere, an inert atmosphere such as argon, or a vacuumed atmosphere and the reducing atmosphere is an atmosphere containing hydrogen gas.

14. The method for producing a substrate with photocatalytic film according to claim 12 or 13, wherein the heat treatment is carried out to control the surface resistance such that the surface resistance of the photocatalytic film is reduced to a value of $10^9 \Omega/\square$ or more.

15. The method for producing a substrate with photocatalytic film according to claim 14, wherein the heat treatment is carried out to control the surface resistance such that the

surface resistance of the photocatalytic film is reduced to a value of $10^{10} \Omega/\square$ or more.

16. The method for producing a substrate with photocatalytic film according to claim 9, wherein in the case that the surface resistance of the photocatalytic film after said coating is less than $10^9 \Omega/\square$, the heat treatment is carried out in an oxidizing atmosphere.

17. The method for producing a substrate with photocatalytic film according to claim 16, wherein the heat treatment is carried out to control the surface resistance such that the surface resistance of the photocatalytic film is increased to a value of $10^{13} \Omega/\square$ or less.

18. The method for producing a substrate with photocatalytic film according to claim 17, wherein the heat treatment is carried out to control the surface resistance such that the surface resistance of the photocatalytic film is increased to a value of $10^{10} \Omega/\square$ or more.

19. The method for producing a substrate with photocatalytic film according to any one of claims 9 to 18, wherein the heating temperature in the heat treatment step is from 200 to 350°C.

20. The method for producing a substrate with photocatalytic film according to any one of claims 9 to 18, wherein the heating temperature in the heat treatment step is from 200 to 300°C.

21. The method for producing a substrate with photocatalytic film according to any one of claims 9 to 20, wherein the target containing titanium contains at least one of niobium, aluminum, iron and nickel as a by-component.

22. The method for producing a substrate with photocatalytic film according to claim 21, wherein a by-component is contained at 0.1 to 3 % by weight of the metallic titanium.

23. The method for producing a substrate with photocatalytic film according to any one of claims 9 to 22, further comprises the step of coating any one of niobium oxide film, aluminum oxide film, iron oxide film and nickel oxide film on the substrate by sputtering a target containing any one of niobium, aluminum, iron and nickel in an atmosphere at reduced pressure before coating the photocatalytic film.

24. The method for producing a substrate with photocatalytic film according to any one of claims 9 to 23, wherein the substrate temperature is less than 200°C during coating the photocatalytic film on the substrate by sputtering.
